**ERDAS Imagine (Leica Geosystems)**

### **Section IIb: Examples of Public Domain Software's Handling of ASTER Geo-Referencing**

**HDF-EOS-to-GeoTiff (HEG)**

## **Introduction**

All image processing software packages employ distinctive procedures for geo-referencing and projecting image data. Some software packages have incorporated specific import routines that geo-reference ASTER data on ingest, however, most have not. The purpose of this document, as delineated in 2 sections, is two-fold:

- First, it provides a general overview of all the issues and components necessary to geo-reference the data in most application software. This is done without specific reference to any particular image processing or GIS software system.
- Next it provides examples of how ASTER geo-referencing is handled by a few of the COTS and public domain software packages.

## **Section I: General Overview of ASTER Geo-Referencing**

This section provides a general overview of ASTER geo-referencing focusing on the following:

- Accessing ASTER Level-1B Metadata
- Specific Metadata Attributes Required for Geo-Referencing ASTER Level-1B Data
- ASTER Level-1B Geo-Referencing Methodology
  - Unique Features of ASTER Level-1B Data
    - Pixel Reference Location
    - Path- or Satellite-Orientation of an ASTER Level-1B Image
    - Ascending and Descending Orbital Paths
    - Geometric Correction Table
    - Geodetic versus Geocentric Coordinates

### **Accessing ASTER Level-1B Metadata**

The information needed to geo-register ASTER Level-1B data is located within the “embedded” metadata (i.e., the metadata contained within the header of the ASTER image data). To access that metadata you will need software capable of reading HDF-EOS-formatted data. A list of commercial and public domain software that handle HDF-EOS is available from [http://lpdaac.usgs.gov/landdaac/tools/hdf/tools\\_table.asp](http://lpdaac.usgs.gov/landdaac/tools/hdf/tools_table.asp). Note that the “.met” file accompanying the ASTER data file does NOT contain all the required information to geo-reference ASTER data, and therefore, we suggest utilizing the embedded hdf metadata.

## Specific Metadata Attributes Required for Geo-Referencing ASTER Level-1B Data

Depending on your software, any or all of the following information may be necessary to geo-reference your ASTER Level-1B image:

Category	Name as Referenced in the Embedded HDF Metadata File	HDF-EOS Subcategory	Description
Scene Corner Coordinates	SCENEFOURCORNERS	productmetadata.0	This denotes the coordinates of the upper-left, upper-right, lower-left and lower-right corners of the scene (latitude and longitude) where: lat: geodetic latitude long: geodetic longitude Unit: Degrees
Map Projection	MAPPROJECTIONNAME  Or  MPMETHOD (band#)	coremetadata.0  productmetadata.v productmetadata.s productmetadata.t	The name of the mapping method for the data. The available map projections are: Equi-Rectangular Lambert Conformal Conic Polar Stereographic Space Oblique Mercator, and Universal Transverse Mercator ----- Map Projection Method: 'EQRECT', 'LAMCC', 'PS', 'SOM', or 'UTM',
Datum	Not specified in the metadata	Not specified in the metadata	WGS84 (for all ASTER data processed at GDS)
Zone (UTM)	UTMZONECODE (band#)	productmetadata.v productmetadata.s productmetadata.t	For VNIR, SWIR and TIR: Zone code for UTM projection (when mapping without UTM: 0 fixed). If southern zone is intended, use negative values
Number of Pixels and Lines	IMAGEDATAINFORMATION	productmetadata.v productmetadata.s productmetadata.t	VNIR: 4980 pixels x 4200 lines (1 BPP)* VNIR (3B): 4980 pixels x 4600 lines (1 BPP) SWIR: 2490 pixels x 2100 lines (1 BPP) TIR: 830 pixels x 700 lines (2 BPP) *BPP: Bytes Per Pixels
Rotation Angle	MAPORIENTATIONANGLE	productmetadata.0	This denotes the angle between the path-oriented image and the map-oriented image within the range -180.0 to 180.0 Unit: Degrees
Cell Size	SPATIALRESOLUTION	productmetadata.0	The nominal spatial resolution:

			VNIR: 15 SWIR: 30 TIR: 90 Unit: Meters
Resampling Method	RESMETHOD (band#)	productmetadata.v productmetadata.s productmetadata.t	Resampling Method: CC: Cubic Convolution BL: Bilinear NN: Nearest Neighbor

### ASTER Level-1B Geo-Referencing Methodology

How one geo-registers an ASTER Level-1B image will vary depending on what image processing software package one uses. The following is a generic description of the process independent of any particular image processing system. All the required attributes for geo-registering an ASTER Level-1B image are available from the embedded metadata in the hdf file and include:

- SCENEFOURCORNERS
- MAPORIENTATIONANGLE
- PROCESSINGPARAMETERS (Projection information)
  - MPMETHOD
  - UTMZONECODE
  - RESMETHOD

SCENEFOURCORNERS represent the geodetic latitude and longitude coordinates (UPPERLEFT, UPPERRIGHT, LOWERLEFT, LOWERRIGHT) of the ASTER Level-1B scene.

The MAPORIENTATIONANGLE denotes the angle of rotation between the path-oriented image and the transformed map-projected coordinates. Ranging from  $-180^\circ$  to  $+180^\circ$ , it provides the amount by which the ASTER Level-1B image is rotated from True North.

The PROCESSINGPARAMETERS object group lists a number of attributes among which MPMETHOD lists the projection used and UTMZONECODE provides the zone information. The PROCESSINGPARAMETERS object group is numbered 1 through 14 for each of the ASTER bands (VNIR, SWIR and TIR). The component objects within this group are also numbered likewise.

You will have to edit the header information for the chosen set of ASTER Level-1B bands that you need to geo-register. The header information for hdf files are encapsulated within the main hdf file itself (this is different from the external .met file). Your image processing system (assuming it handles the hierarchical data format) will likely have a mechanism to display the embedded header information and save it to an ASCII file, and also edit their attributes.

The steps comprising the process of geo-registering your ASTER image will vary with each application software system, and hence cannot be generalized. But some of the broadly common requirements might include:

- specifying the values for the corner column-row (pixel-line) image coordinates
- specifying the correct pixel resolution for x and y
- specifying the MAPORIENTATIONANGLE value
- specifying the output projection parameters including the projection and its related information, datum etc. Presently, the datum information is not included in the metadata.

Committing the above changes and re-displaying your Level-1B should ensure that the image is displayed in geographic latitude-longitude coordinates. You can further verify the quality of geo-registration by overlaying a reliable vector coverage layer of the same area that has the same projection coordinates as your ASTER Level-1B image.

## **Unique Features of ASTER Level-1B Data**

### ***Pixel Reference Location***

There is a fundamental difference between the alignment of the image bands and how their pixels are referenced. Assuming that we have the full complement of data from all the three sensors (VNIR, SWIR, and TIR), the VNIR Band-2 is used as the reference band, and data for all the three sensors are aligned by the upper-left **corners** of their upper-left pixels. When there are only SWIR and TIR bands present, the SWIR Band-6 is used as the reference band. When a Level-1B data set contains only TIR data, the TIR Band-11 is used as the reference band.

The SceneFourCorners upper-left is calculated using Band-2 of the VNIR (or Band-6 of SWIR or Band-11 of TIR as warranted by the data acquisition), and represents the **center** of the upper left image pixel. You may need to make necessary adjustments to the x and y values representing the centers of any particular sensor's upper-left image pixel depending on how your specific image processing software references the pixel location (see diagram below where "x" is the SceneFourCorners upper-left).

This diagram represents the upper-left pixel of each of the bands of VNIR, SWIR and TIR in an ASTER Level-1B data set

### *Footprint of an ASTER Level-1B Image*

The footprint of an ASTER Level-1B image is somewhat unique when viewed in the context of the alignment of its SceneFourCorners. Only the upper-left pixel of the SceneFourCorners lies within an ASTER Level-1B (or Level-2) image extent. The other three corner coordinates represent locations that are one pixel beyond the extent of the image.

### *Path- or Satellite-Orientation of an ASTER Level-1B Image*

The ASTER instrument aboard the Terra satellite platform orbits the Earth at 10:30 AM local equator-crossing time. This renders day-time orbits to be descending passes while night-time orbits are ascending passes. The MapOrientationAngle denotes the angle of rotation between the path-oriented image and the transformed map-projected coordinates. Ranging from  $-180^\circ$  to  $+180^\circ$ , it provides

the amount by which an ASTER Level-1B image is rotated to or from True North. It is therefore, positive and clock-wise for descending orbits, and negative and counter clock-wise for ascending orbits. This field is present in:

- ASTER Level-1B data sets processed at the Ground Data System (GDS), Japan using version 4.0 (and higher versions) of the Level-1 algorithm, and available from the LP-DAAC in Sioux Falls, SD.
- ASTER Level-2 products produced at the LP-DAAC, in Sioux Falls, SD.

In the case of ASTER Level-1 data produced prior to the implementation of algorithm version 4.0 (before May 2001), MapOrientationAngle is named SceneOrientationAngle (in the hdf metadata), and is measured as the angle from the path-oriented image to north-up. ***If you are using an ASTER Level-1B processed prior to May 2001, using an algorithm version that is less than 4.0 (referred to as PGEVERSION in the hdf metadata), it is important to bear in mind that the SceneOrientationAngle values have reverse signs.***

There are two collection versions of the routinely produced ASTER Level-1 data sets available from the LP-DAAC (Versions 002 and 003). Typically, all data sets produced with algorithm version 4.0 (and higher versions) are available in the version 003 collection while data sets produced with algorithm versions lower than 4.0 are available in the version 002 collection.

The upper-left for an ASTER scene is relative to the orbital path of the Terra satellite (the diagram below relates to Landsat-7 satellite but is also useful in visualizing the orbital paths of the Terra satellite platform).

### ***Ascending and Descending Orbital Paths***

*(Source: Landsat 7 Processing System (LPS) Output Files Data Format Control Book, 510-3FCD/0195, July 1998)*

### ***Geometric Correction Table***

ASTER HDF metadata contains Geometric Correction Tables (GCTs) for each telescope, including the VNIR 3B band. These GCTs are arrays of pixel/line locations and their corresponding geographic coordinates. It is important to remember that for ASTER Level-1A and Level-1B data, the GCTs are in geocentric coordinates. For all ASTER Level-2 products, the GCTs are in geodetic coordinates.

GCTs contain information that are internal to the swath data structures. As part of the geometric correction, each scene is divided into block units, and the processing of the scene is done block by block in both the along-track and cross-track directions. The values for the lattice points constitute coordinates for each lattice block located by their center pixel and their corresponding latitudes and longitudes in geocentric coordinates.

The stepping in each dimension is specified in the structural metadata of the swath. The interval spacing for the GCT begins with (0, 0), and increments by values contained in the HDF metadata fields named ImageLine and ImagePixel.

Example of a VNIR Swath stepping:

VNIR Structural metadata is in a global attribute called StructMetadata.0

```
OBJECT = DimensionMap_1
GeoDimension = GeoTrack
DataDimension = ImageLine
Offset = 0
Increment = 420
END_OBJECT = DimensionMap_1
OBJECT = DimensionMap_2
GeoDimension = GeoXtrack
DataDimension = ImagePixel
Offset = 0
Increment = 498
END_OBJECT = DimensionMap_2
```

The stepping cross-track is 498 pixels and the along-track stepping is 420 pixels. Both Offsets are zero. The 11 x 11 arrays give the locations for the following pixels (using 0 for smallest index):

(line, sample) = (0,0), (0, 498), ...	(0, 4980)
(420,0), (420, 498) ...	(420, 4980)
(840,0) (840, 498) ...	(840, 4980)
.	.
.	.

(3780,0), (3780,498) ... (3780,4980)  
(4200,0) ... (4200, 4980)

ASTER Level-1B and ASTER Level-2 GCT values, and the SceneFourCorners values are both generated from the Level-1B. The SceneFourCorners upper-left matches the GCT (0, 0) out to 6 decimal places. The GCT coordinates are more precise, extending out to 12 or more decimal places. There should be no significant difference between the positional accuracy of the data using either the GCT values as ground control, or the SceneFourCorners upper-left and MapOrientationAngle to orient either the ASTER Level-1B data or Level-2 products.

The equation to convert the swath-based geocentric coordinates to geodetic coordinates is:

$$\text{Geodetic} = \text{Arctan} [(\tan (\text{Latitude})) / 0.99330562]$$

This equation is for the WGS 84 datum only. Geocentric longitudes do not need to be converted to geodetic since they both are the same and they also share the same reference meridian and axis.

### *Geodetic versus Geocentric Coordinates*

Geodetic coordinates specify a location on the Earth's oblate (non-spherical) surface. Geodetic latitude is defined as the angle between the equatorial plane and a line normal to the surface at that location. Geodetic longitude is the angular distance between the location's meridian and the Greenwich meridian.

Geocentric coordinates relate to a reference system where the origin is the center of the Earth. Geocentric latitude is defined by the angle between the equatorial plane and a line from the local position to the intersection of the axis of rotation with the equatorial plane. Geodetic longitude and geocentric longitude are the same because they share the same reference meridian and axis.

## **Section IIa: Examples of COTS Software's Handling of ASTER Geo-Referencing**

### **ENVI 3.5 (RSI)**

ENVI from RSI is an image-processing package that allows you to view and manipulate an ASTER level-1 image. The following is written with the belief that the user is fairly conversant with the handling of all the relevant ENVI modules. If you are new to ENVI, take a look at the following site: <http://www.rsinc.com/envi/FeatureTour.asp> or refer to the ENVI User Guide and/or Tutorials.

*If you use **ENVI version 3.4**, refer to the following URL on how to manually enter all the required map registration information in ENVI: <http://www.rsinc.com/services/techtip.asp?ttid=3347>*

*If you use **ENVI 3.6 and higher versions**, you don't need to manually edit the ENVI header file. As part of geo-referencing, you need to rotate the image using the value of the MapOrientationAngle in the embedded HDF metadata.*

*If you use **ENVI version 3.6**, follow this sequence: Basic Tools > Rotate/Flip Data > Rotation Input File > Rotation Parameters > OK.*

*You will have to manually type in the MapOrientationAngle value in the Rotation Parameters dialog box, specify the output file name, and hit OK.*

*If you use **ENVI 4.0 and higher versions**, follow the same sequence but the only difference is that the MapOrientationAngle is already read in automatically. You only need to specify the output file name, and hit OK.*

*[Graphics describing these steps is provided in 2.2]*

The major steps involved in importing an ASTER image into ENVI are summarized below with 5 sets of graphics. The numbered steps correspond to each of the graphics. The last section describes converting map coordinates for ASTER higher-level products.

1. Edit the ENVI header file to facilitate importing the ASTER scene.

**File > Edit ENVI Header > Edit Header Input File > Open File > Header Info > Edit Attributes > Map information > Map Registration > Projection Selection > Select Geographic Datum > Map Information**

- Change line and sample of UL to 1.5, 1.5
- Change datum from NAD27 to WGS84
- Change projection name to UTM
- Pick the appropriate UTM zone for the geographic location of your ASTER scene

2. Re-project to create a “north-up” image from the existing path-oriented image.

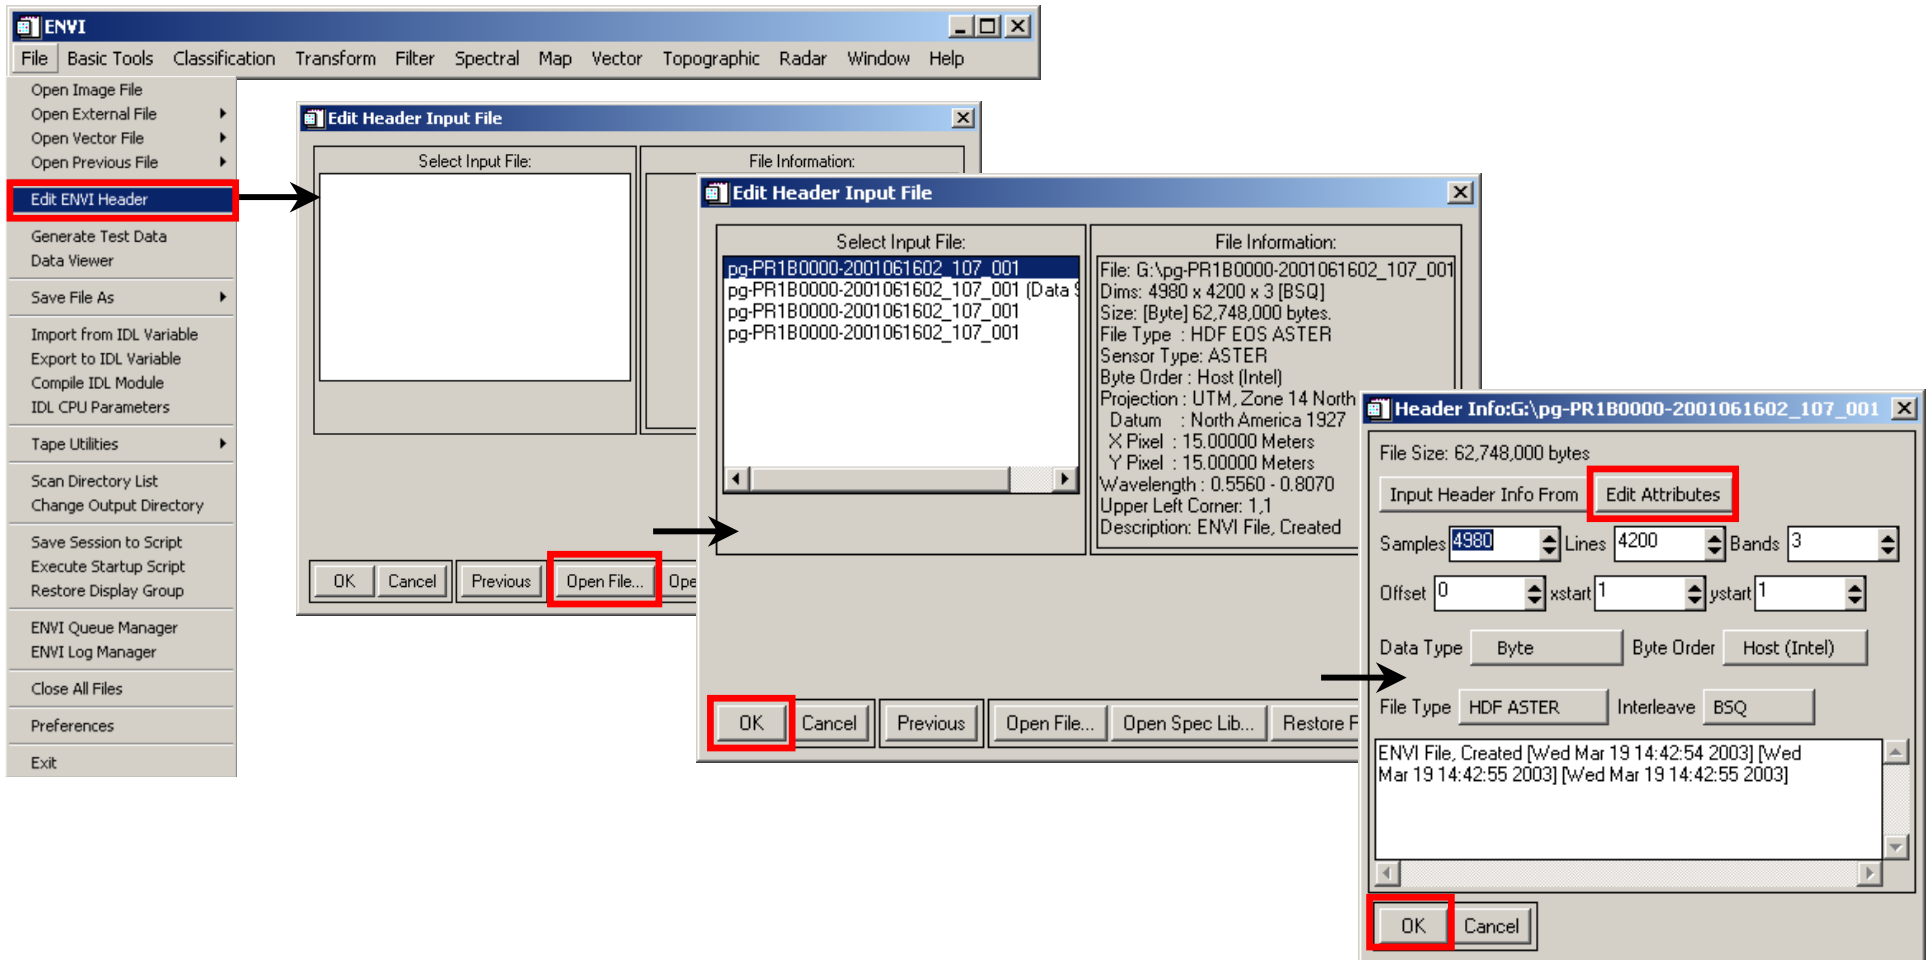

**Map > Convert Map Projection Input Image > Convert Map Projection Parameters > Registration Parameters > Image Registration**

The output is a north-up geo-referenced image. Figure 2.1 depicts a path-oriented versus a north-up image of the ASTER scene.

3. If you so desire, save the output ENVI image file to an alternative format.

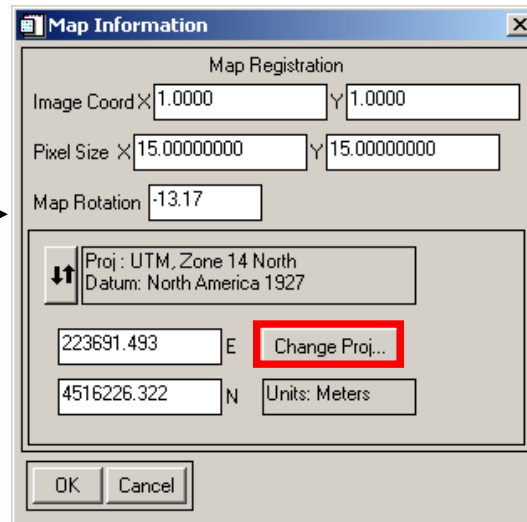

**File > Save Image As > Image File > Output File Type**

# 1. Edit the ENVI Header File

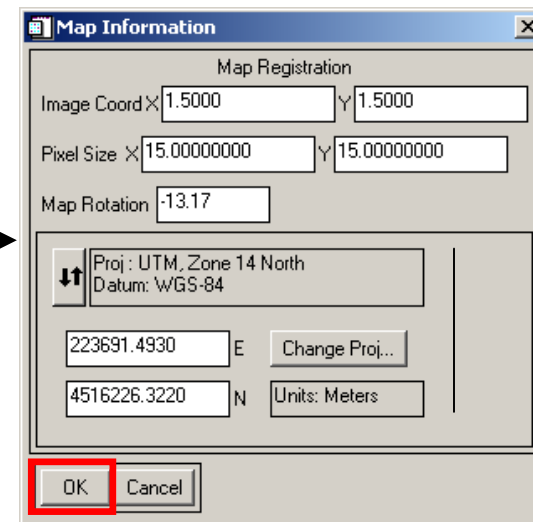

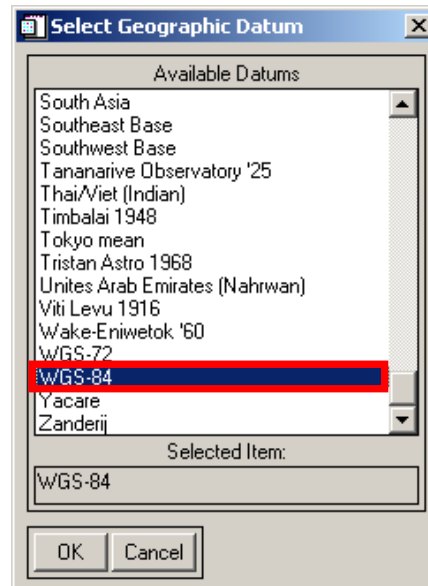

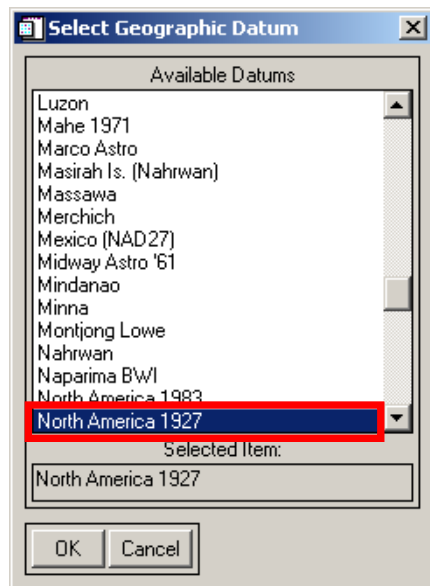

## 1. Editing the ENVI Header File continued ...

Change Image Coord X, Y to 1.5, 1.5  
Click 'Change Projection'

## 2. Re-project to create a “North-up” image

The process is shown in four sequential screenshots:

- ENVI Main Window:** The **Map** menu is open, and **Convert Map Projection** is highlighted with a red box.
- Convert Map Projection Parameters:** The dialog shows the input projection as UTM, Zone 14 North. The output projection is selected as **UTM** (highlighted with a red box). Other settings include Datum: WGS-84, Units: Meters, and Zone: 14 North.
- Registration Parameters:** The dialog shows the registration method as **Polynomial** (Degree 1) and resampling as **Nearest Neighbor**. The output image path is set to **E:\ASPRS picture\swof\_NE** (highlighted with a red box).
- Image Registration:** The progress bar shows the registration is 81% complete.

*2.1 Path-oriented versus North-up image*

Path-oriented image

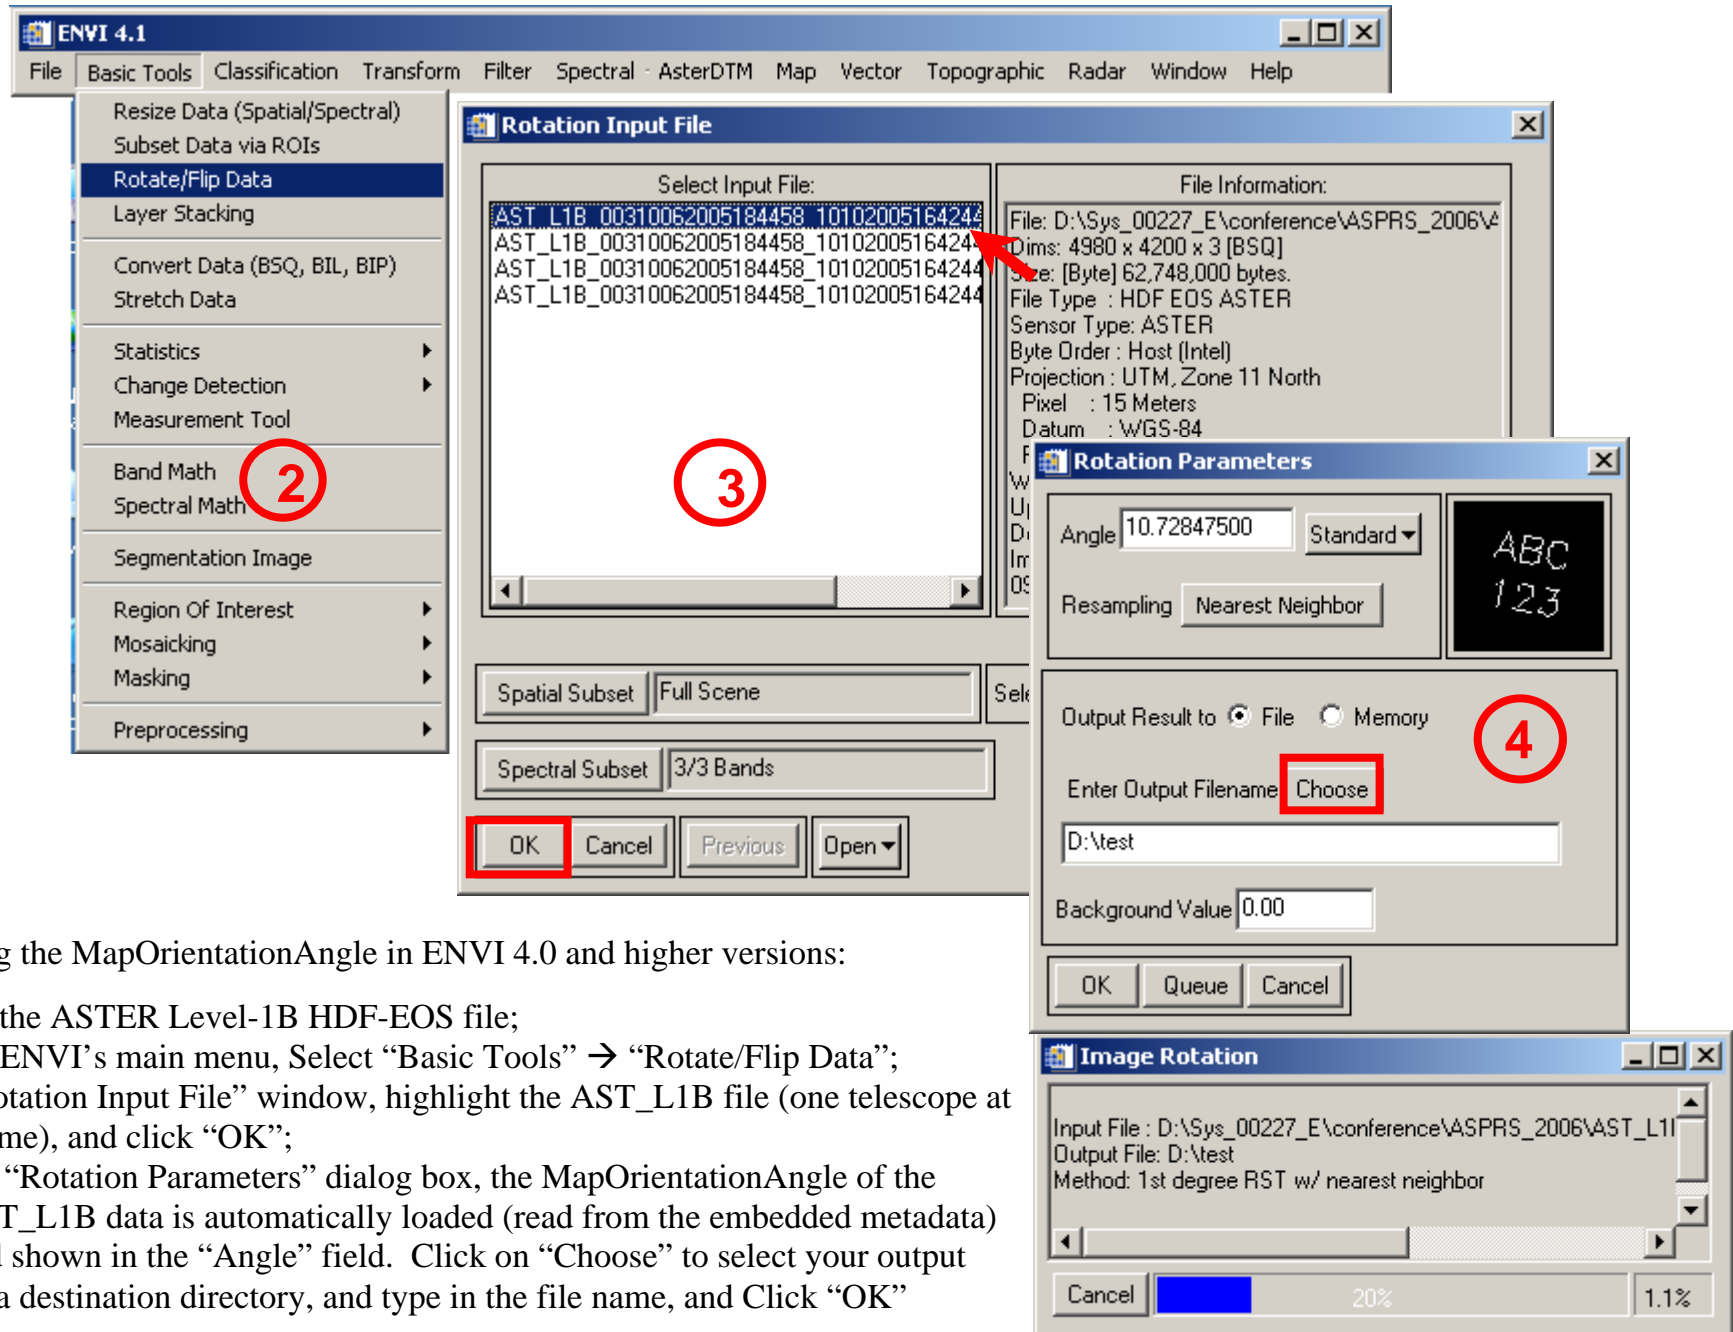

North-up image in UTM projection

## 2.2 Applying the MapOrientationAngle (Only for ENVI 4.0 and higher versions)

## 2.2 (cont...) Path-oriented versus a North-up image

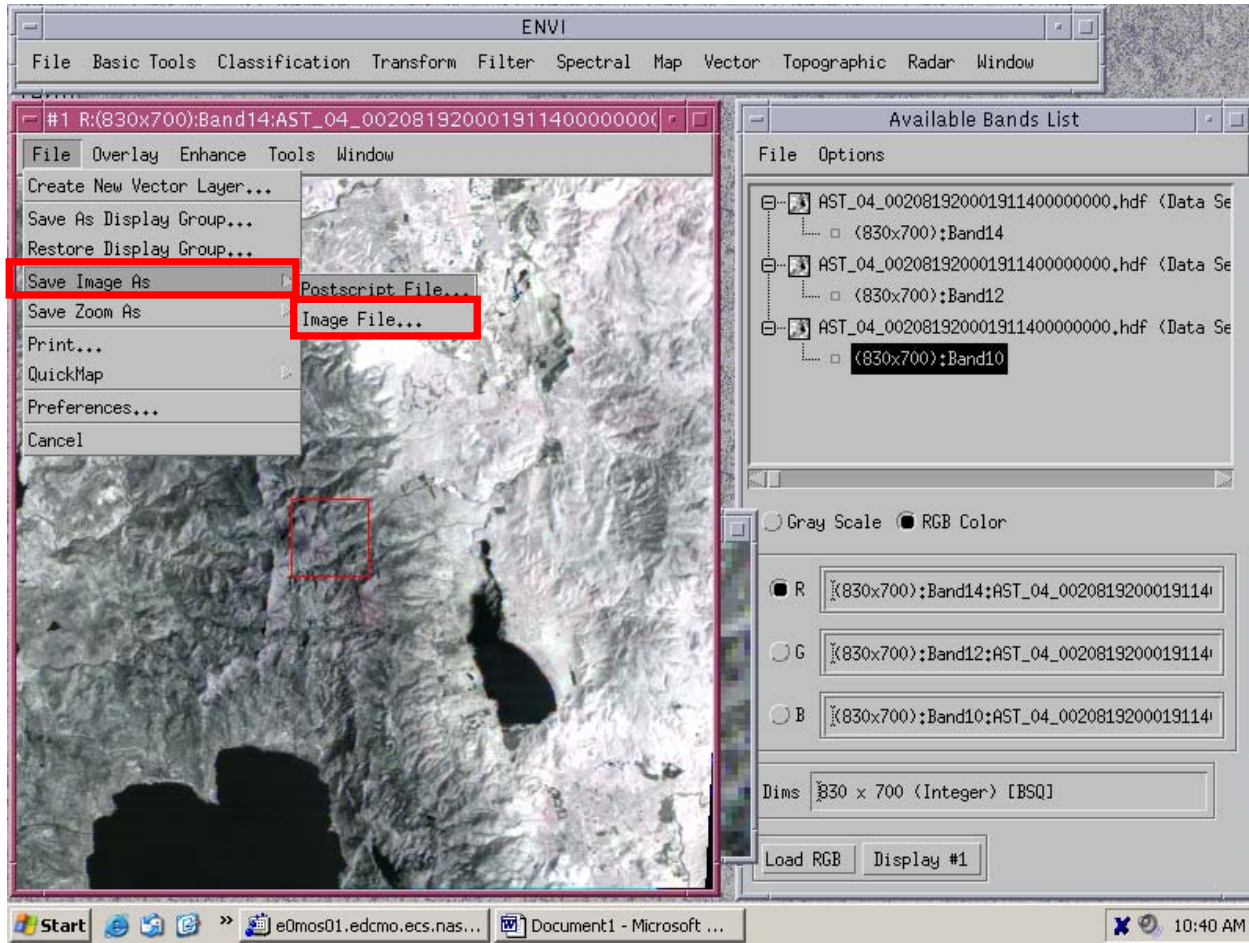

ASTER Level-1B image registered to satellite path-oriented North in UTM projection, WGS 84 Datum

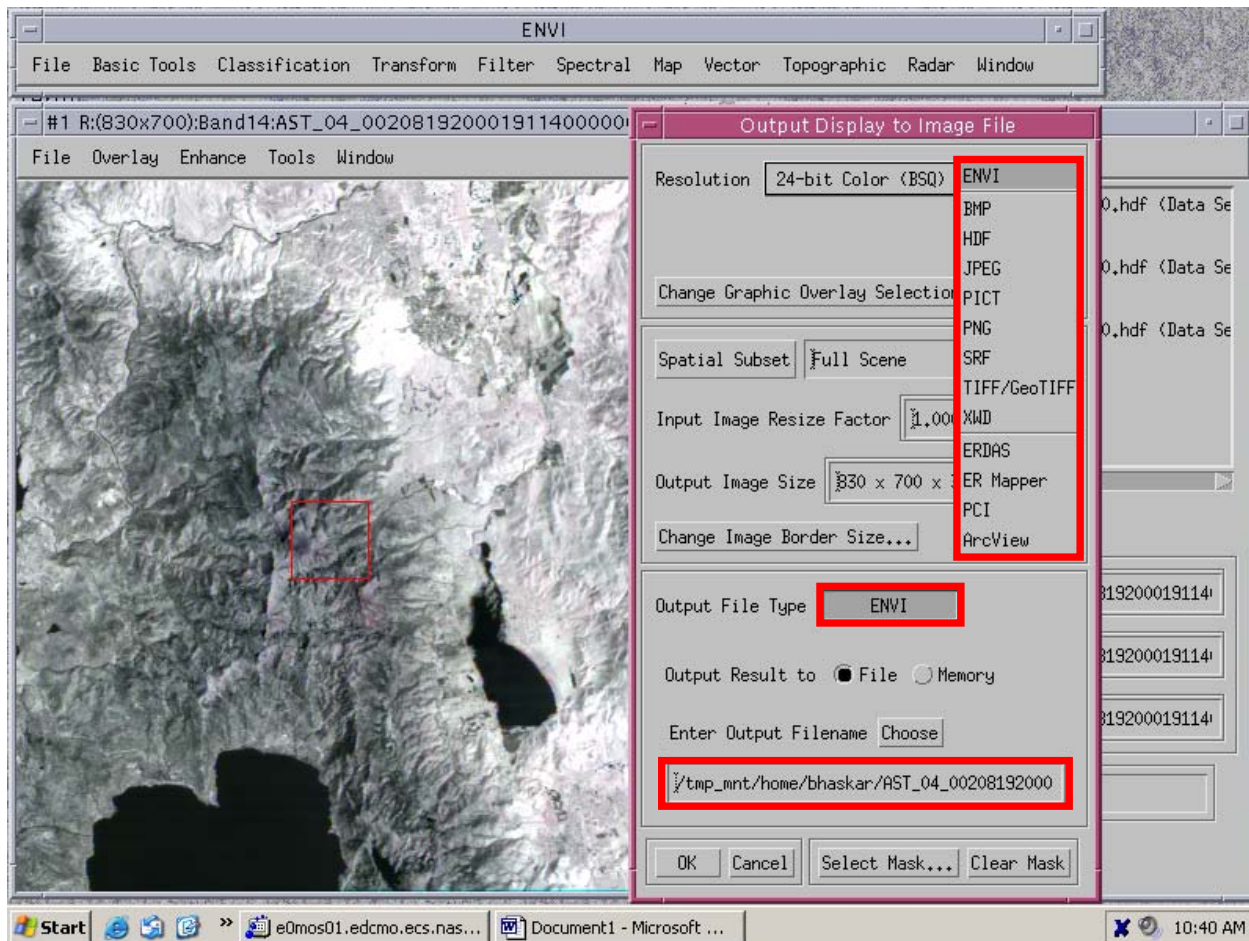

ASTER Level-1B image rotated North-up with the application of the MapOrientation angle (UTM projection, WGS 84 Datum)

### 3. Save the output image in an alternative format

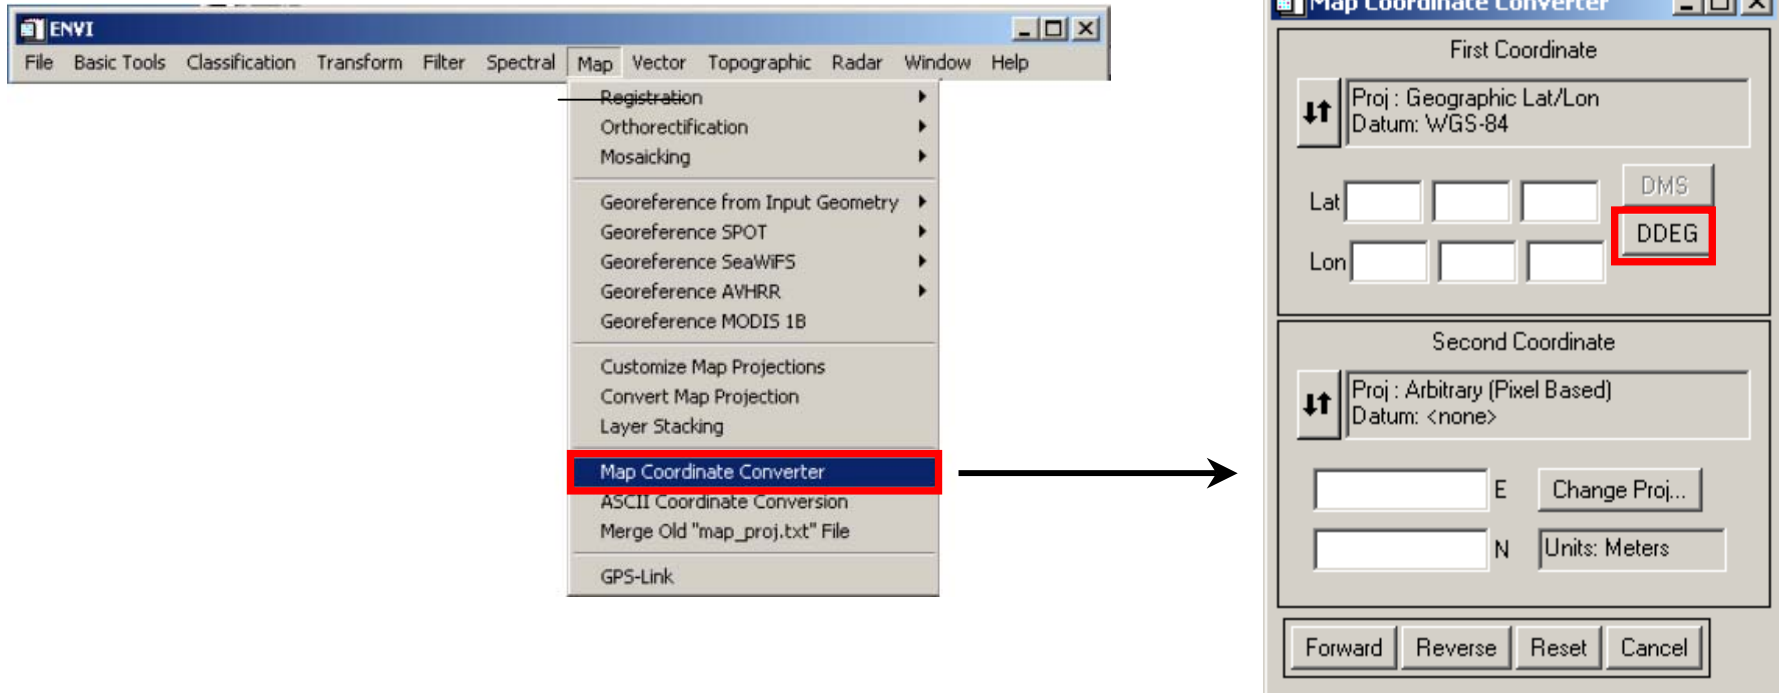

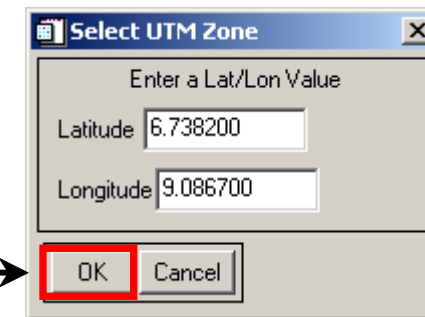

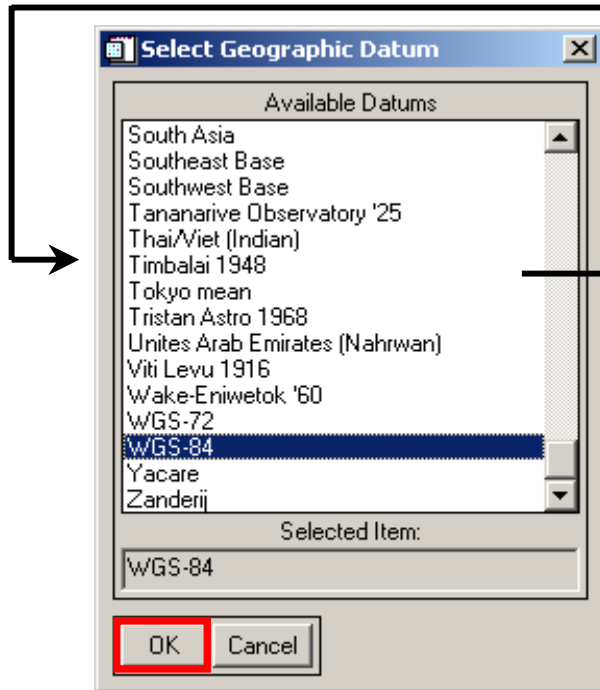

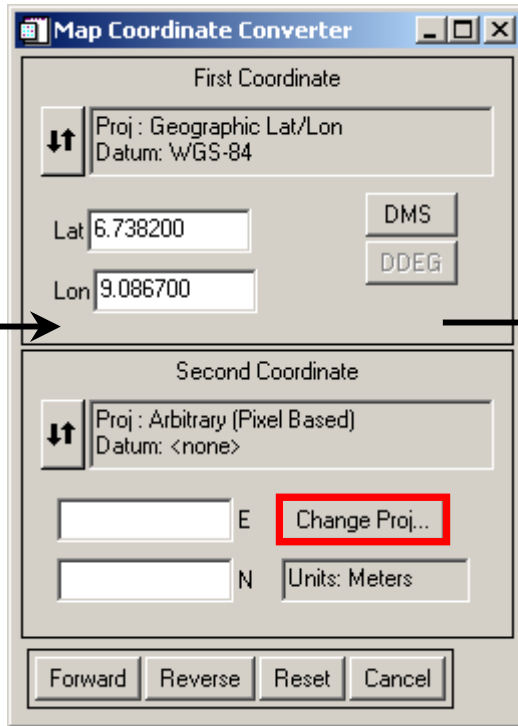

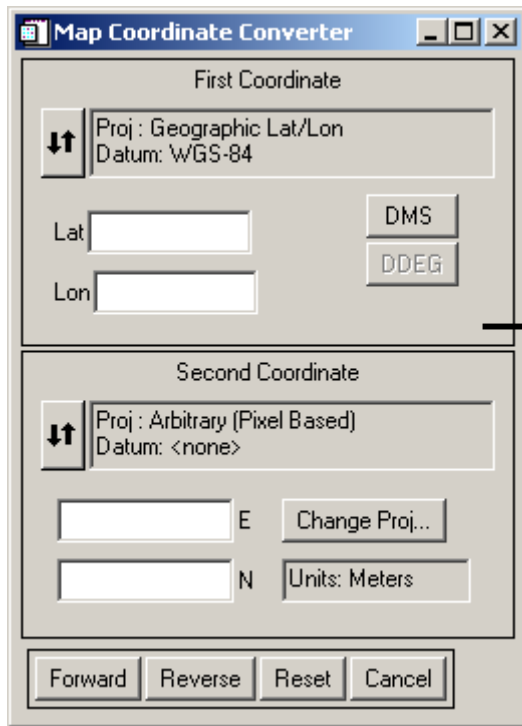

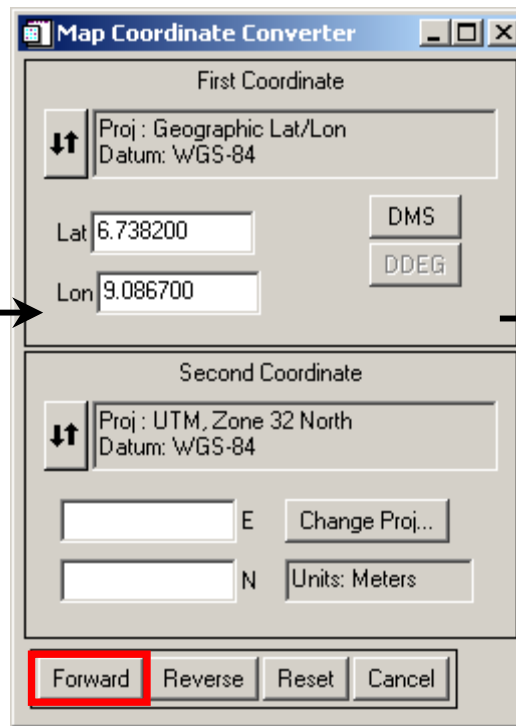

#### 4. Converting Map Coordinates

If you are attempting to geo-reference either an ASTER higher-level product (DEM, reflectance, radiance etc.) or an ASTER expedited data set, you will be required to convert the latitude and longitude coordinates into Easting and Northing values. That can

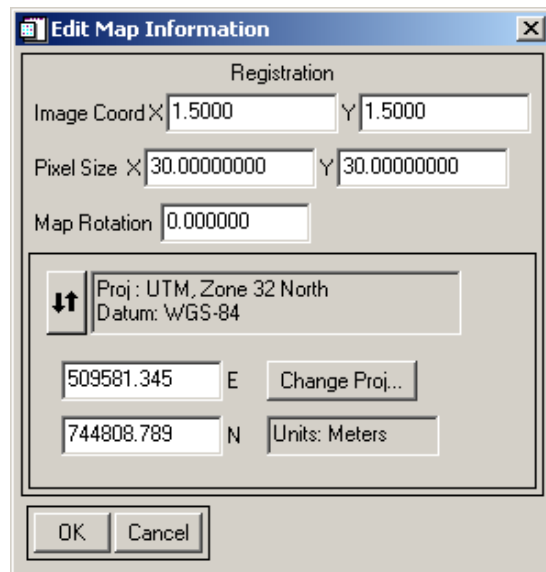

be accomplished in ENVI using the **Map Coordinate Converter** under the **Map** module. The following set of graphics describe that process.

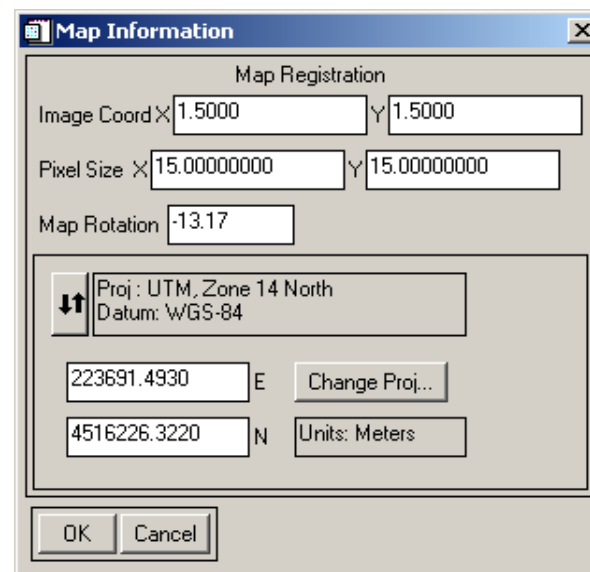

ENVI Header File: ASTER DEM

ENVI Header File: ASTER Reflectance (VNIR)

## ERDAS Imagine 8.5 (Leica Geosystems)

The ERDAS Imagine suite of image processing software also handles the importing and geo-referencing of ASTER data sets. With Imagine 8.5, you need to get the ASTER EOS HDF Importer upgrade patch. *This is standard in Imagine 8.6 and 8.7.* If you are not familiar with the Imagine suite, visit: [http://www.gis.leica-geosystems.com/Products/product\\_details.asp?productid=2](http://www.gis.leica-geosystems.com/Products/product_details.asp?productid=2)  
The following steps outline the process of importing an ASTER level-1B data set into Imagine:

1. Import the ASTER image with first-order transformation correction.

### **Import > ASTER EOS HDF Format Importer > Correction > Correction Parameters**

- Initiate the Import module from the main list of modules
- Choose **ASTER EOS-HDF Format** as the file type and provide the input and output file names
- Select **Correction** (from the **ASTER EOS HDF Format Importer** dialog box), and check the **Write Transform to Image** box, with default Transformation Order of **1** to import the ASTER HDF file
- Assuming your data set has the full complement of VNIR, SWIR and TIR bands, you start with the VNIR bands. To import the SWIR and TIR bands, click on **Next Image** on the **ASTER EOS HDF Format Importer** dialog with the **Correction** option.
- The output image will be in Lat/Lon geographic coordinate system
- You can view key attributes from the embedded HDF metadata by invoking **ImageInfo** from your Viewer, and selecting **HDFGlobalAttributes** (the fifth tab from the left)

2. Re-project the ASTER image using the DataPrep module.

### **DataPrep > Reproject Images ...> Reproject Images**

- Initiate the DataPrep module from the main list of modules
  - Select **Reproject Images ...**, and provide input file and output image name
  - Specify the output projection name and related details. For instance:
    - Projection name: UTM
    - Datum: WGS84
    - UTM Zone Number: ...
    - Output image pixel size (X,Y), units, & re-sampling method: 15m, 15m, Cubic Convolution ...
3. The output is a north-up geo-referenced image. Figure 3 depicts a path-oriented versus a north-up image of the ASTER scene. If you so desire, save the output imagine image file to an alternative format with the Export module

### **Export > Input > Output**

# 1. Import the ASTER scene with first-order transformation correction

The screenshot illustrates the workflow in ERDAS IMAGINE 8.5 for importing an ASTER scene with first-order transformation correction. The process involves several dialog boxes:

- Import/Export Dialog:** The 'Import' radio button is selected. The 'Type' is set to 'ASTER EOS HDF Format'. The 'Media' is set to 'File'. The 'Input File' is 'baltimore.hdf' and the 'Output File' is 'baltimore.img'. The 'Input File' list shows several files, including 'Baltimore.hdf'.
- ASTER EOS HDF Format Importer Dialog:** This dialog provides input data information: Platform: AM-1, Instrument: ASTER, Product Type: ASTL1B, Data Field: VNIR\_Swath. It also shows dimensions: No Columns: 4200, No Rows: 4980, No Layers: 3. The 'Correction...' button is highlighted with a red box.
- Correction Parameters Dialog:** This dialog is used to specify correction parameters. The 'Rectification' tab is active. The 'Write Transform to Image' checkbox is checked. The 'Transformation Order' is set to 1. The 'Write GCP File' checkbox is unchecked.

Arrows indicate the flow of the process: from the 'Import/Export' dialog to the 'ASTER EOS HDF Format Importer' dialog, and then to the 'Correction Parameters' dialog.

## 2. Re-project the ASTER image using the DataPrep module

The screenshot displays the ERDAS IMAGINE 8.5 software interface. The top menu bar includes Session, Main, Tools, Utilities, and Help. The toolbar contains icons for Credits, Viewer, Import, DataPrep (highlighted with a red box), Composer, Interpreter, Catalog, Classifier, Modeler, Vector, Radar, Virtual GIS, and OrthoBASE.

The Data Preparation dialog box is open, showing a list of operations. The 'Reproject Images...' option is highlighted with a red box. An arrow points from this option to the 'Reproject Images' dialog box.

The 'Reproject Images' dialog box is shown in two states. The left state shows the 'Output Projection' set to 'Oblique Mercator (Bessel)' and 'Output Cell Sizes' set to X: 0.000198 and Y: 0.000162. The right state shows the 'Output Projection' set to 'UTM Zone 18 (Range 78W - 72W)' and 'Output Cell Sizes' set to X: 15.000000 and Y: 15.000000. The 'OK' button in the right state is highlighted with a red box. An arrow points from the 'Output Cell Sizes' field in the left state to the 'Output Cell Sizes' field in the right state.

The 'Reproject Images' dialog box includes the following fields and options:

- Input File: (\*.img) - baltimore.img
- Output File: (\*.img) - baltimore\_utm.img
- Output Projection: Switzerland (Categories), Oblique Mercator (Bessel) (Projection)
- Units: meters (Units),  Ignore Zero in Stats.
- Output Cell Sizes: X: 0.000198, Y: 0.000162
- Resample Method: Nearest Neighbor
- Rigorous Transformation,  Polynomial Approximation
- Maximum poly order: 3, Tolerance (pixels): 0.100
- If tolerance exceeded:  Continue Approximation,  Rigorous Transformation
- Buttons: OK, Batch, Cancel, Help

Options when approximation tolerance exceeded

*3. Path-oriented versus north-up Imagine output images*

**ASTER HDF file imported with first-order transformation correction in geographic latitude/longitude coordinates**

**ASTER HDF file projected from geographic to north-up UTM**

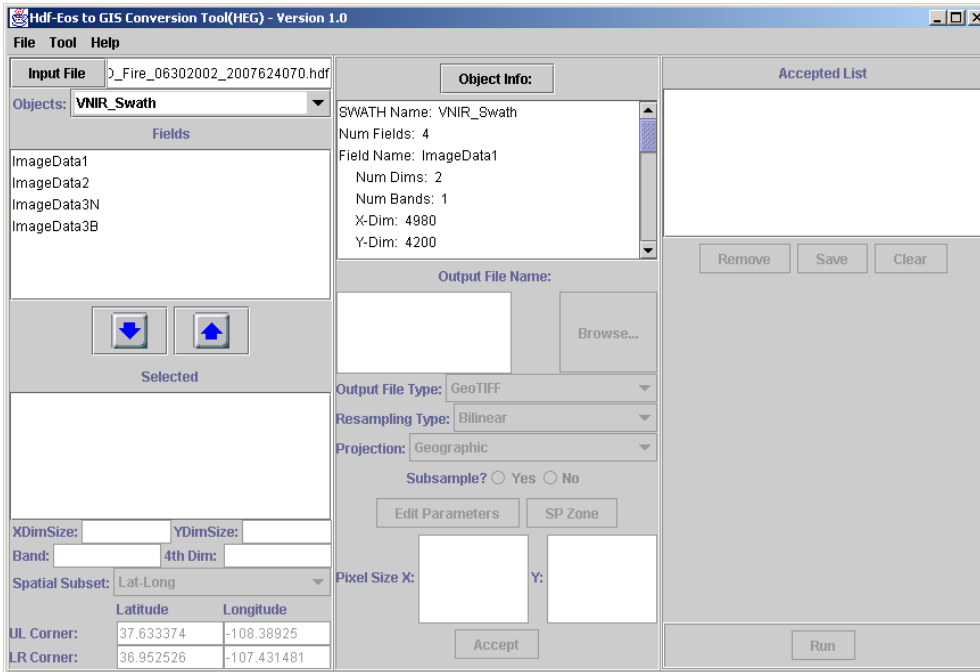

## **Section IIb: Examples of Public Domain Software's Handling of ASTER Geo-Referencing**

There are a number of public domain packages that have been developed to handle the evolution of the various Terra-derived data sets and their derived products. The novelty of the HDF-EOS data structure has resulted in several streams of development and implementation especially at a time when the major commercial image processing and GIS vendors have been slow to provide support. As a result, several packages and browsers exist that vary in their functionality and sophistication. The functionality one such package, the HDF-to-GeoTiff (HEG), is described below.

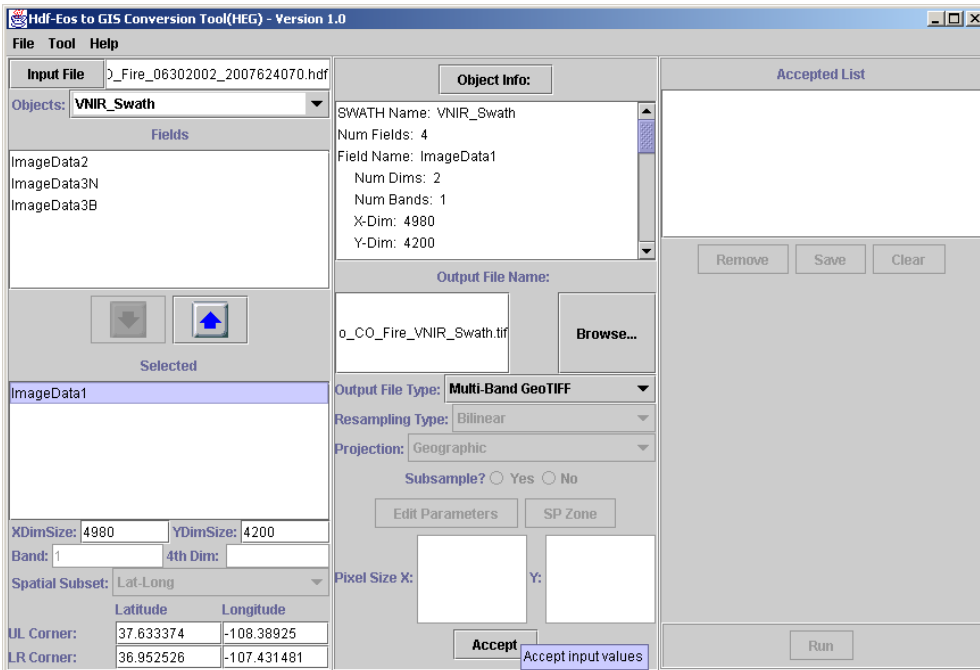

### **HDF-EOS-to-GeoTiff (HEG)**

The HDF-EOS Development Team at ECS, Landover, developed the HEG tool (<http://newsroom.gsfc.nasa.gov/sdptoolkit/HEG/HEGHome.html>) to handle a variety of ASTER, MODIS and MISR data sets and derived products. It allows you to convert from HDF-EOS to GeoTiff, native binary or HDF-EOS Grid formats. It also has re-projection, re-sampling, sub-setting and mosaicking functionalities. The tool is being fine-tuned to fix a number of anomalies. Following is a brief overview of how you would handle an ASTER image within HEG.

1. Ensure that your ASTER image has a .hdf extension.
2. Assuming that you have successfully set up HEG on your system, open the hdf file from the file menu.
3. The first set of image bands (VNIR) is listed as a VNIR Swath object, and the bands are listed as ImageData1, Image Data2, ImageData3N and ImageData3B under Fields in the first (of three columns) of the HEG interface.
4. Highlight ImageData1 and click on the down-arrow below it to select that particular band.
5. In the second column of the interface, specify the output file type (one of [GeoTiff](#), [Binary](#), [Multi-Band GeoTiff](#), [HDF-EOS](#)).
6. Specify your re-sampling (one of [Bilinear](#), [Nearest Neighbor](#), and [Cubic Convolution](#)) and projection options (one of [Geographic](#), [Polar Stereographic](#), [Universal Transverse Mercator](#), and [Space Oblique Mercator](#)), and click **Accept** on the bottom. The selected ImageData1 will appear in the **Accepted List** on the third column of the interface.
7. Repeat steps 4, 5, and 6 to add the other bands (ImageData2 and ImageData3) in the **Accepted List**.
8. Click **Run** on the bottom of the third column.

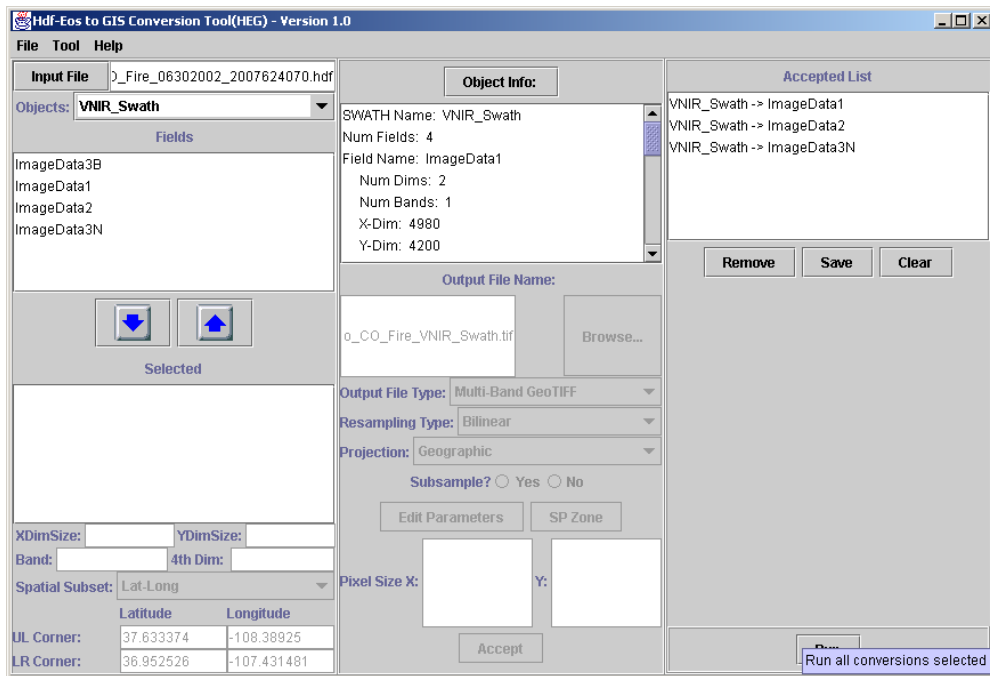

Step 2

Steps 3, 4

Steps 5, 6

Steps 7, 8
